

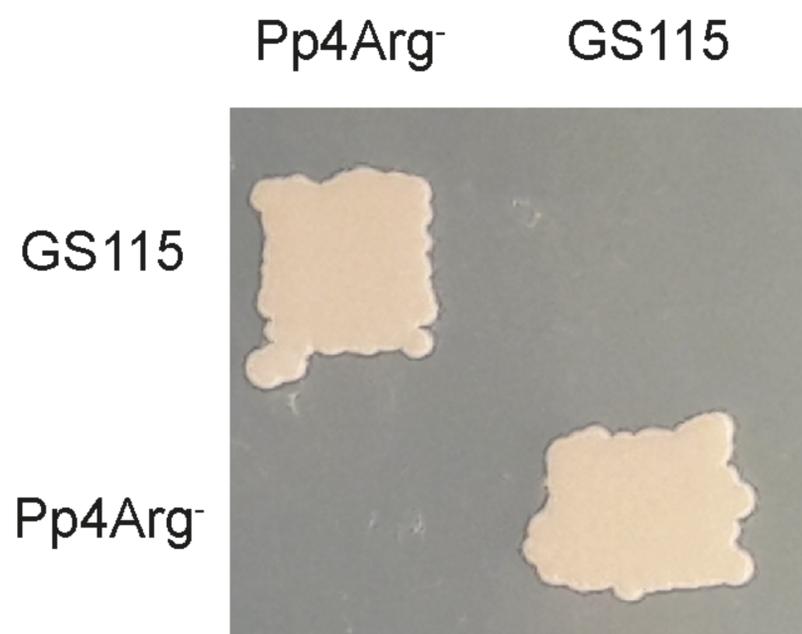

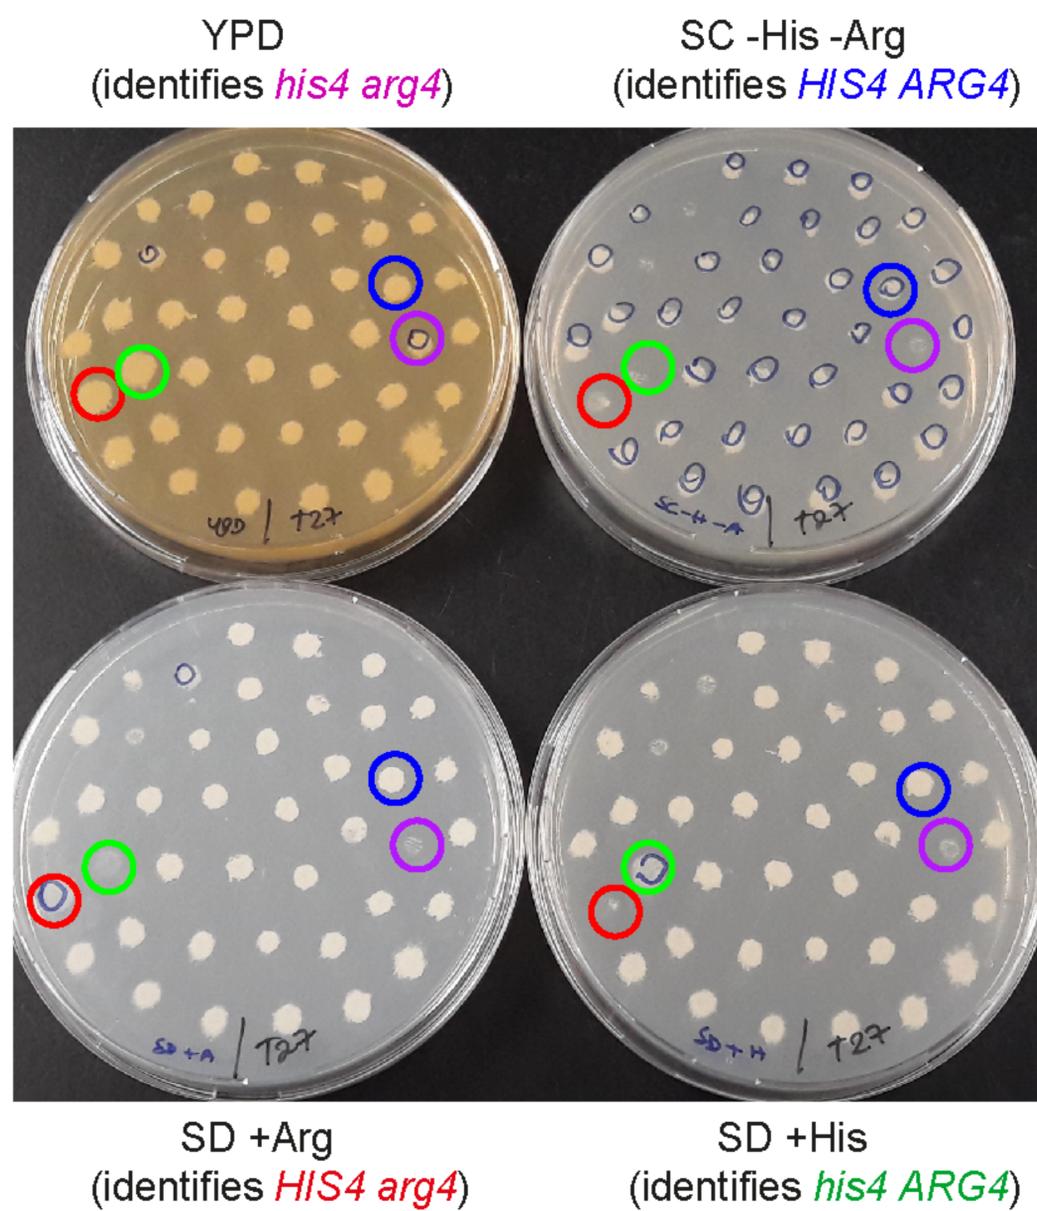

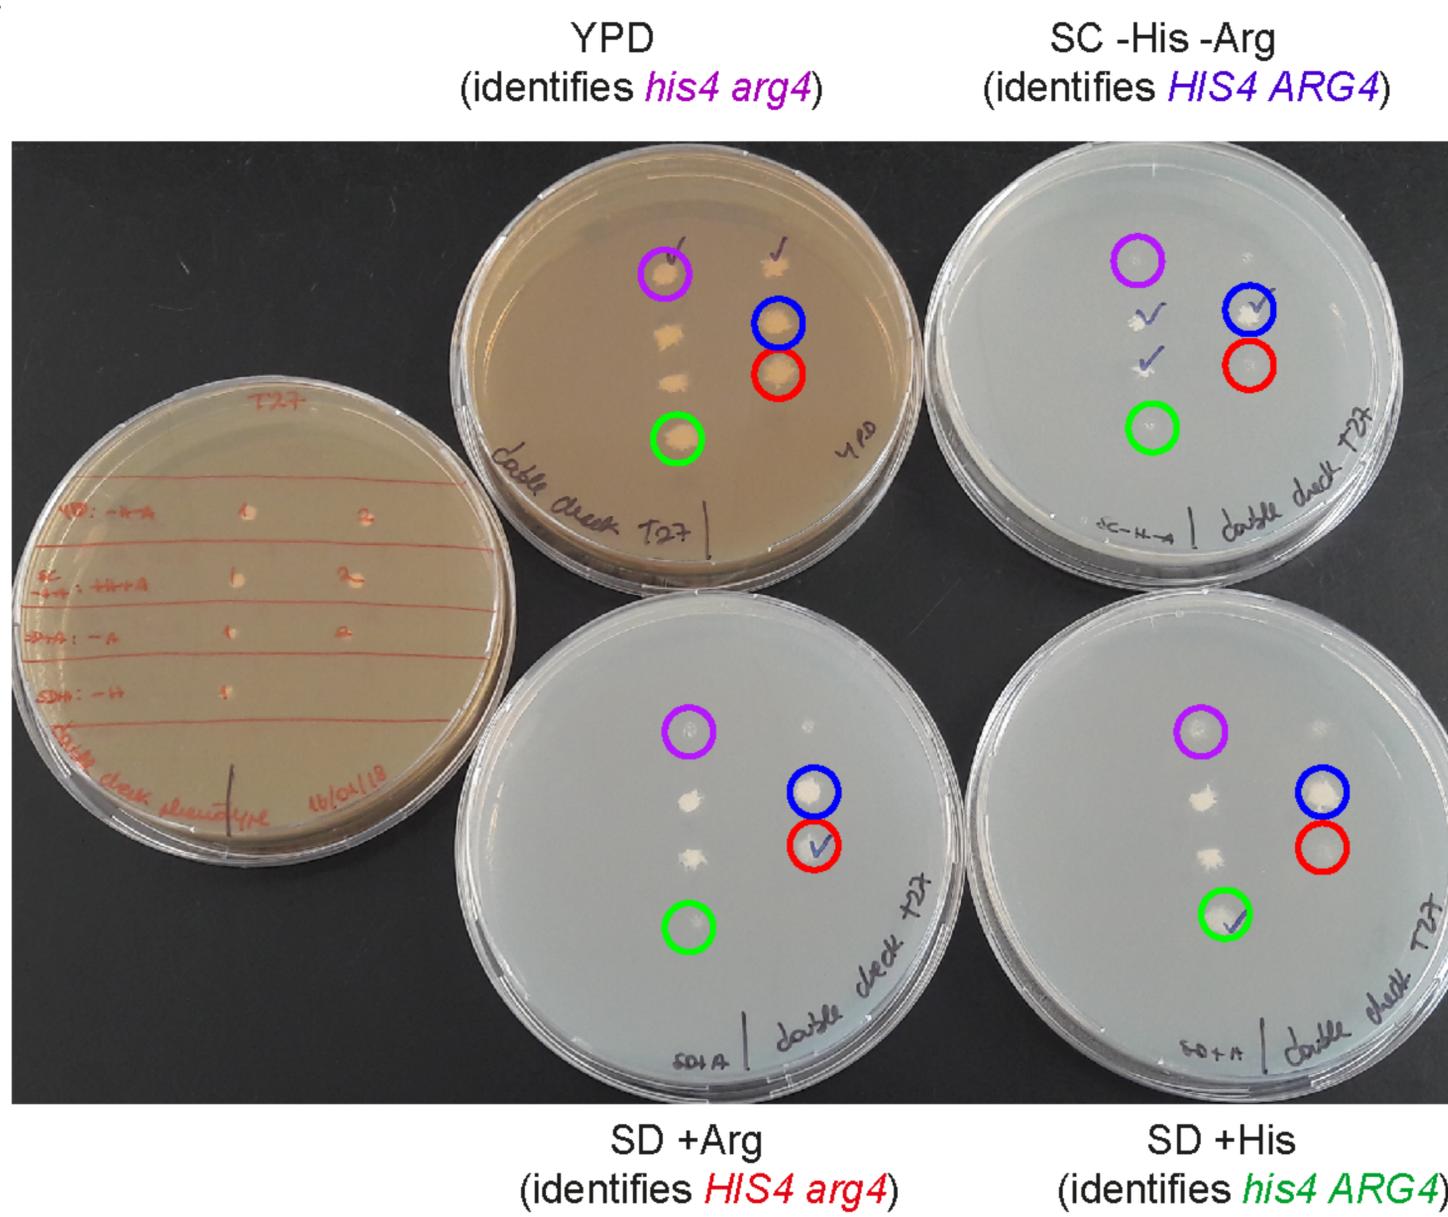

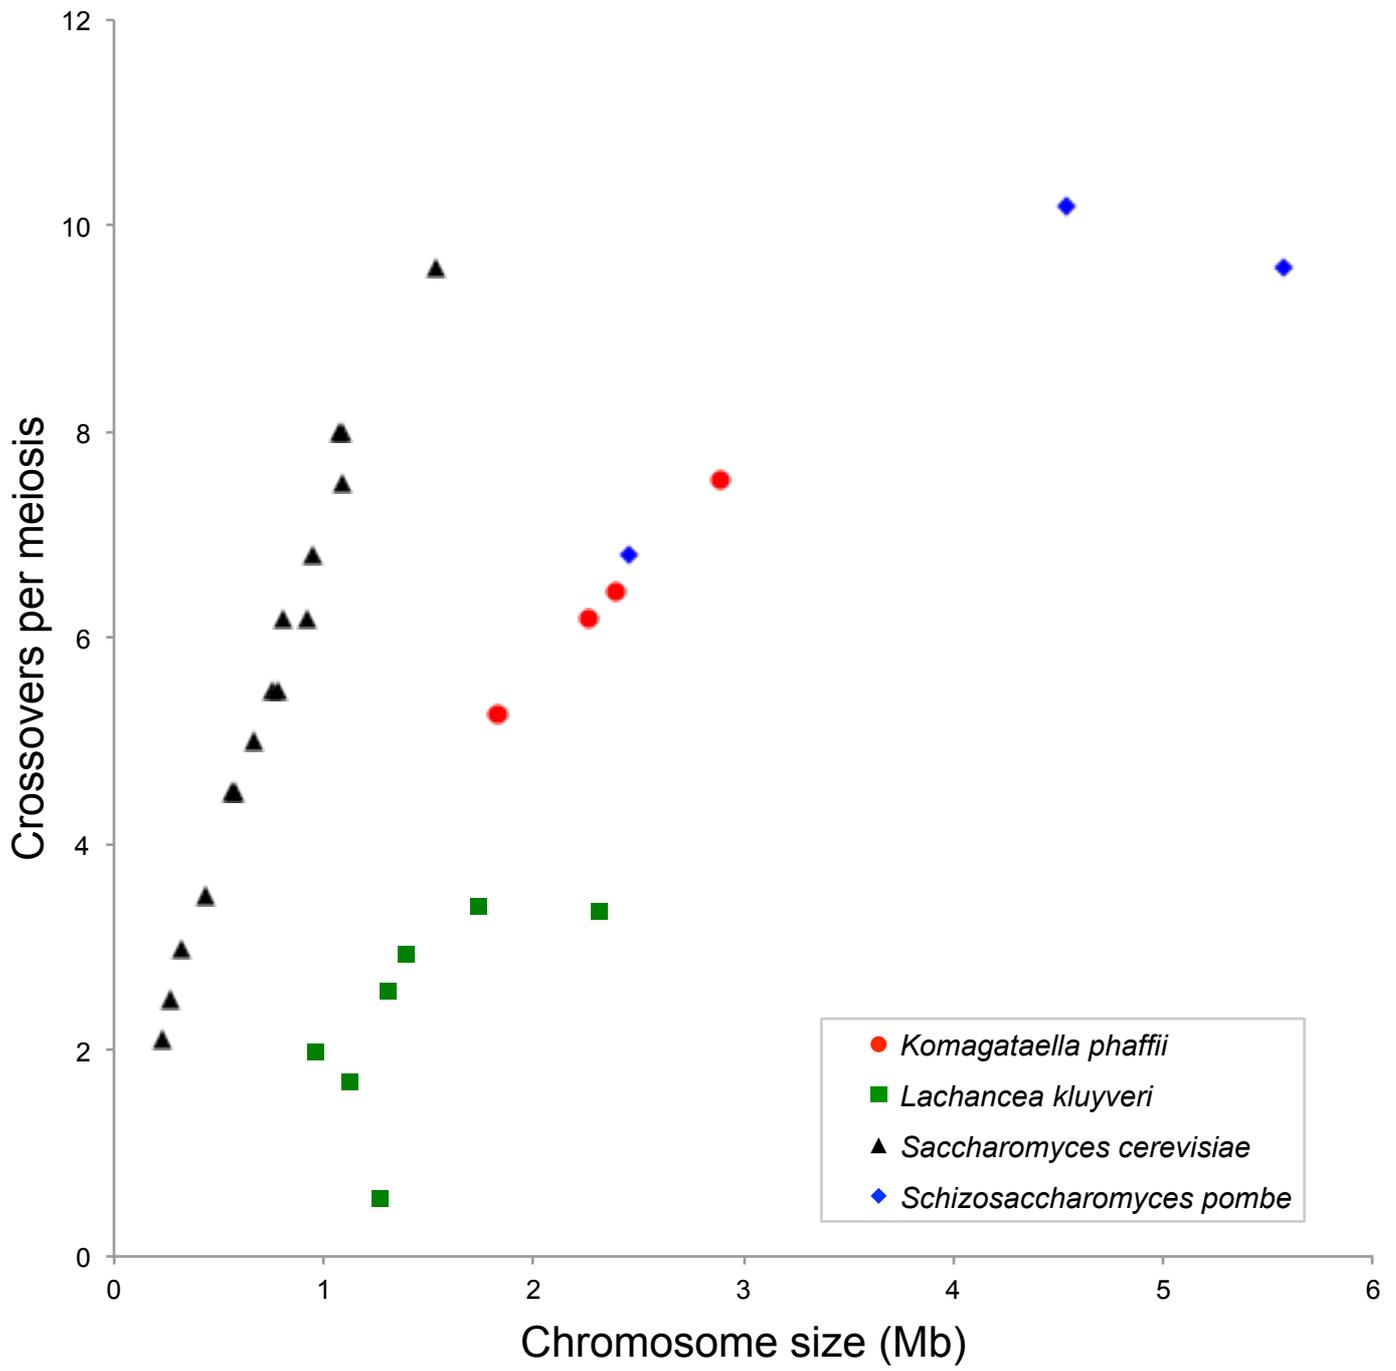

**Figure S1. Crossing of parental strains and identification of segregant genotypes. (a)**

Crossing of parental strains. Parallel streaks of the two parental strains Pp4Arg<sup>-</sup> and GS115 were made on a YPD plate, and then replica-plated twice perpendicularly onto a mating plate (NaKG +His +Arg) to make a grid pattern. After growth, the mating plate was then replica plated onto the SC -His -Arg selection plate shown. Diploid cells (His<sup>+</sup> Arg<sup>+</sup>) grow at the intersections of the streaks. **(b)** Initial identification of segregants from Tetrad 27, by replica plating onto 4 media. An example of each class of segregant is circled. **(c)** Verification of segregant genotypes from Tetrad 27 by a second round of replica plating.

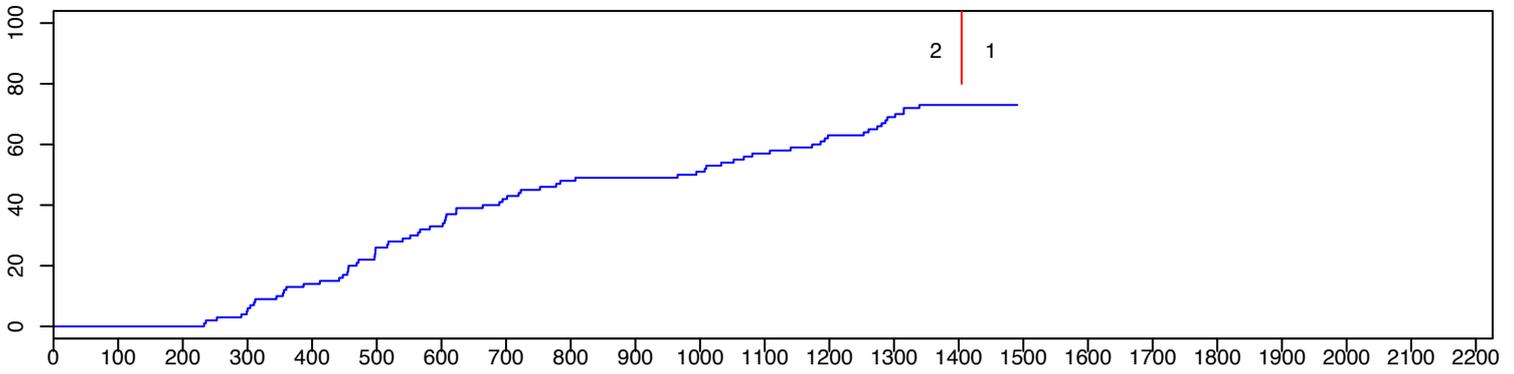

**Figure S2.** Relationship between chromosome size and the average number of crossovers per meiosis on that chromosome, in four ascomycete yeast species: *K. phaffii* (this study), *L. kluyveri* [23], *S. cerevisiae* [22], and *Sch. pombe* [25]. For *Sch. pombe*, we considered only the 10 F1 segregants in [25], omitting F2 segregants, and assumed that the actual number of crossovers in the ascus was twice the number of crossovers detected in the single segregant that was sequenced from each ascus; hence the results for *Sch. pombe* differ from [23]. The number of crossovers on the largest *Sch. pombe* chromosome may be abnormally low due to a large inversion [25]. For *L. kluyveri*, chromosome C has the lowest number of crossovers, and its low rate has been attributed to the origin of most of this chromosome from an ancient introgression event [23].

**Figure S3. Locations of crossovers on each chromosome, as a function of their distance from the centromere.** Red lines and numbers 1-2 indicate the number of chromosome arms that exist at any particular distance. All chromosomes are plotted on the same horizontal scale. Obligatory crossovers in the *ARG4-HIS4* interval on chromosome 1 were excluded from this analysis (for Tetrad 22 and Trio 20, which have two crossovers in this interval, we arbitrarily designated the more centromere-proximal crossover as non-obligatory and the more distal one as obligatory).
